Introduction to Computer Science: Programming Methodology

Lecture 7 Object Oriented Programming II

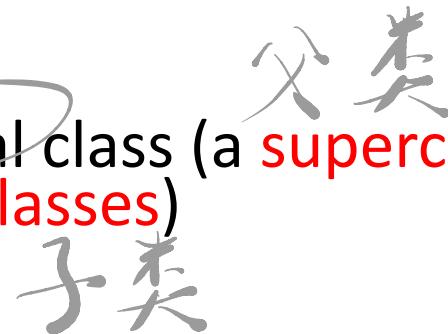

Prof. Junhua Zhao
School of Science and Engineering

继承 Inheritance

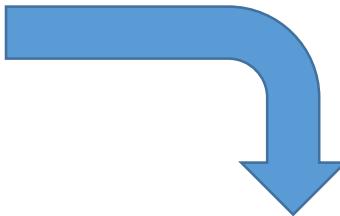

- The object-oriented programming couples data and methods together into objects
- The object oriented approach combines the power of the functional programming with an added dimension that integrates data with operations into objects
- Object-oriented programming (OOP) allows you to define new classes from existing classes. This is called **inheritance**
- Inheritance extends the power of the object-oriented paradigm by adding an important and powerful feature for reusing software

Superclass and subclass

- Inheritance enables you to define a general class (a **superclass**) and later extend it to more specialized classes (**subclasses**)
- You use a class to model objects of the same type. Different classes may have some **common properties and behaviours** that you can generalize in a class
- Inheritance enables you to define a general class and later extend it to define more specialized classes
- The specialized classes **inherit** the properties and methods from the general class.

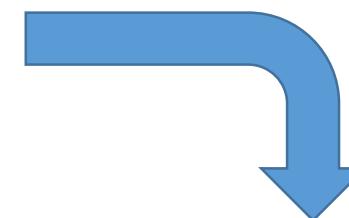

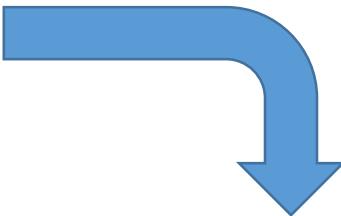

Example: Human -> Chinese -> Cantonese

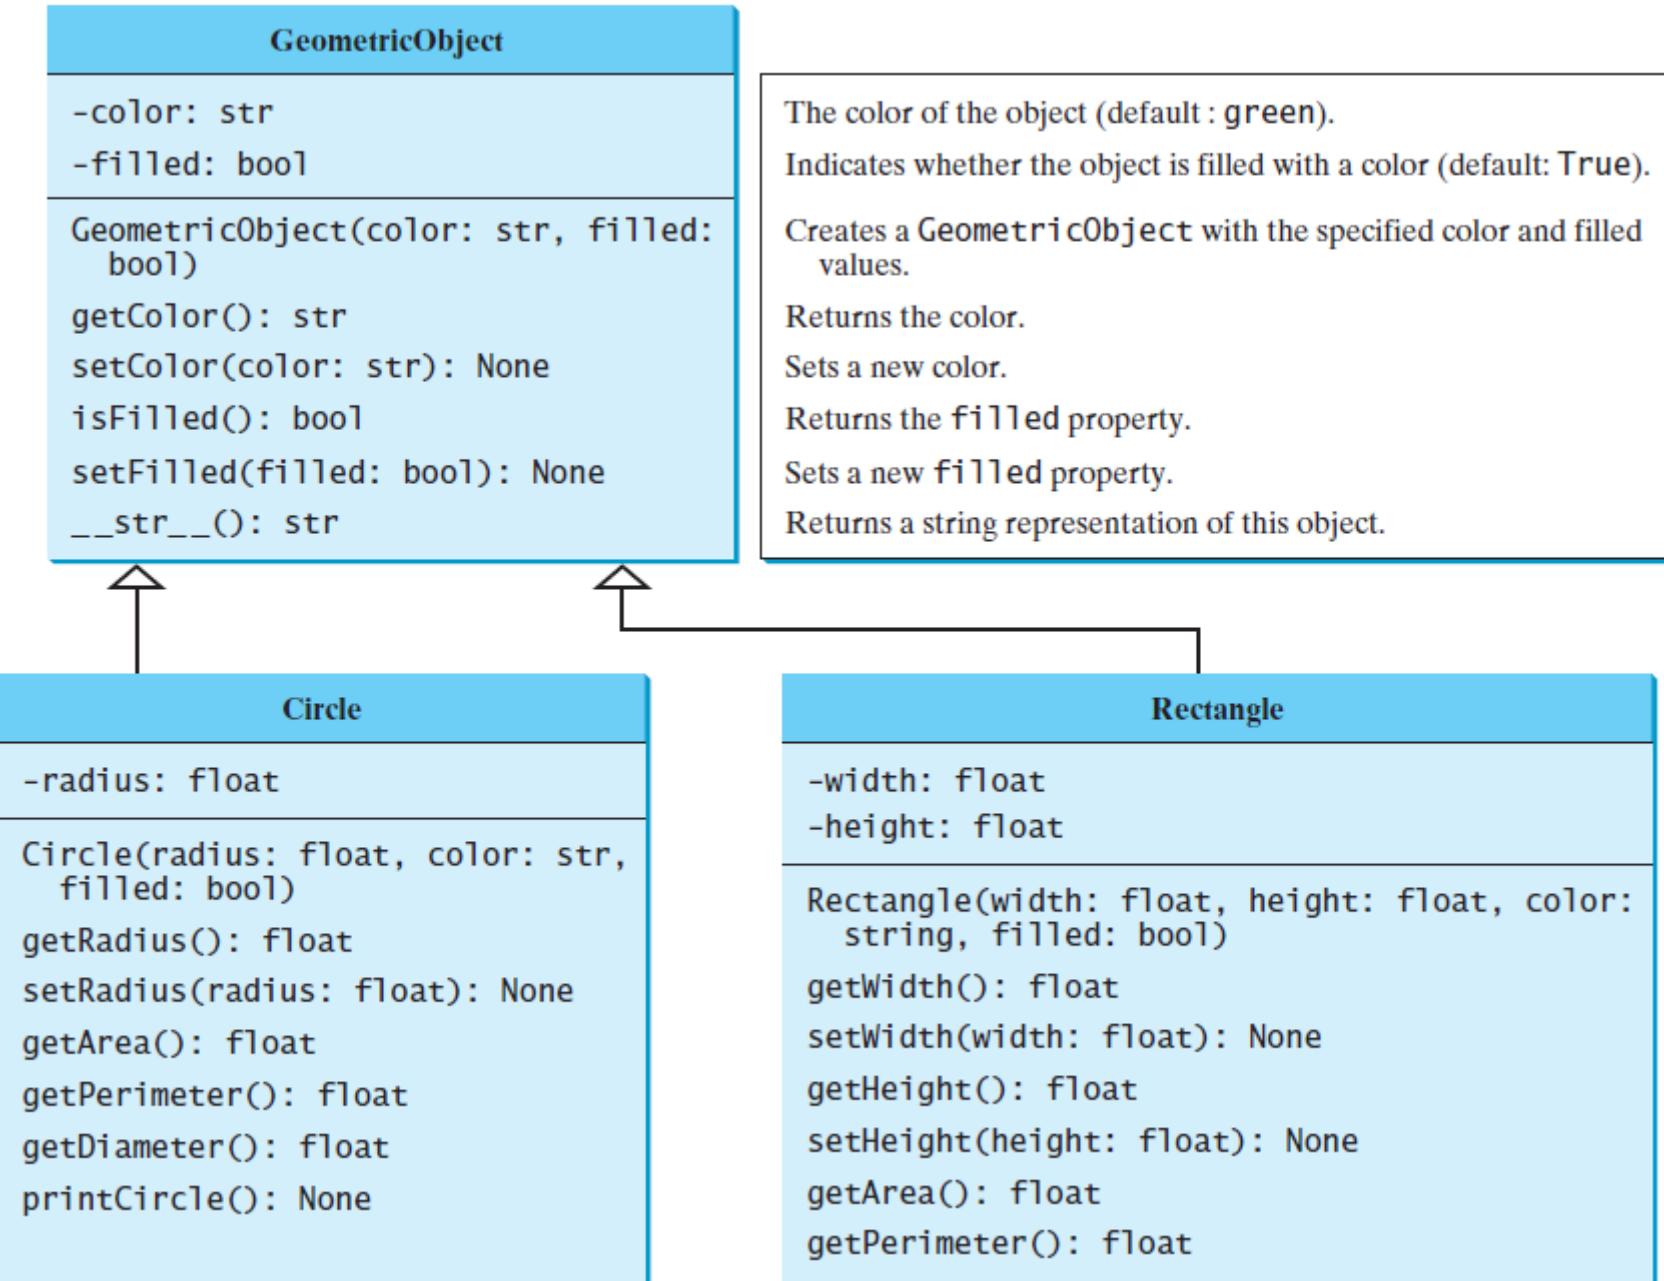

cipic.com/

Example: Human -> Star -> Movie Star

大不同,
啊大不同

Geometric Object and two of its subclasses

The code for GeometricObject

```
class GeometricObject:  
    def __init__(self, color = "green", filled = True):  
        self.__color = color  
        self.__filled = filled  
  
    def getColor(self):  
        return self.__color  
  
    def setColor(self, color):  
        self.__color = color  
  
    def isFilled(self):  
        return self.__filled  
  
    def setFilled(self, filled):  
        self.__filled = filled  
  
    def __str__(self):  
        return "color: " + self.__color + \  
              " and filled: " + str(self.__filled)
```

GeometricObject class
initializer
data fields

getColor

setColor

isFilled

A screenshot of a computer monitor displaying two windows. On the left is a code editor showing a Python script named `GeometricObj.py`. The code defines a class `GeometricObj` with an `__init__` method and a `str` method. A hand-drawn arrow points from the handwritten note below to the `str` method. On the right is a terminal window showing a Python session. The user types `a=13.7658`, `round(a)`, which outputs `14`. Then `a=12.3456`, `b=round(a)`, which outputs `12`. Finally, `b=round(a*100)`, `b`, which outputs `1235`, and `b/100`, which outputs `12.35`. The terminal then shows a traceback for a `TypeError` when trying to print the object `g`.

```
class GeometricObj:  
    def __init__(self, color = 'green', filled = True):  
        self._color=color  
        self._filled=filled  
    def str_(self):  
        return "color:'"+self._color+"' filled:"+str(self._filled)  
g = GeometricObj()  
print(g)  
  
print an object, print the  
return of --str--()
```

```
>>> a=13.7658  
>>> round(a)  
14  
>>> a=12.3456  
>>> b=round(a)  
>>> b  
12  
>>> b=round(a*100)  
>>> b  
1235  
>>> b/100  
12.35  
>>>  
==== RESTART: C:/Users/stul.CUHSZ/Desktop/  
Traceback (most recent call last):  
  File "C:/Users/stul.CUHSZ/Desktop/  
    print(g)  
  File "C:/Users/stul.CUHSZ/Desktop/  
    return 'color:' +self._color' fi  
TypeError: can only concatenate str (not "NoneType")  
>>>  
==== RESTART: C:/Users/stul.CUHSZ/Desktop/  
color:green filled:True  
>>>
```

The code for Circle class

- A subclass inherits accessible data fields and methods from its superclass, but it can also have **other data fields and methods**

尚未定义，但
Python will automatically inherit all methods.

```
from GeometricObject import GeometricObject
import math # math.pi is used in the class

class Circle(GeometricObject):
    def __init__(self, radius):
        super().__init__()
        self.__radius = radius
    def getRadius(self):
        return self.__radius
    def setRadius(self, radius):
        self.__radius = radius
    def getArea(self):
        return self.__radius * self.__radius * math.pi
    def getDiameter(self):
        return 2 * self.__radius
    def getPerimeter(self):
        return 2 * self.__radius * math.pi
    def printCircle(self):
        print(self.__str__() + " radius: " + str(self.__radius))
```

~~class Circle(GeometricObject):~~ →
~~def __init__(self, radius):~~ → calling the init() of superclass
~~super().__init__()~~ → Python will not automatically inherit data fields

Inheritance syntax

- The **Circle** class is derived from the **GeometricObject** class, based on the following syntax

```
subclass           superclass
      ↓             ↓
class Circle(GeometricObject):
```

- Circle** class inherits the **GeometricObject** class, thus inheriting the methods **getColor**, **setColor**, **isFilled**, **setFilled**, and **__str__**
- The **printCircle** method invokes the **__str__()** method defined to obtain properties defined in the superclass

The code for rectangle class

```
from GeometricObject import GeometricObject

class Rectangle(GeometricObject):
    def __init__(self, width = 1, height = 1):
        super().__init__()
        self.__width = width
        self.__height = height

    def getWidth(self):
        return self.__width

    def setWidth(self, width):
        self.__width = width

    def getHeight(self):
        return self.__height

    def setHeight(self, height):
        self.__height = self.__height

    def getArea(self):
        return self.__width * self.__height

    def getPerimeter(self):
        return 2 * (self.__width + self.__height)
```

extend superclass
initializer
superclass initializer
methods

The code for testing Circle and Rectangle

```
from CircleFromGeometricObject import Circle
from RectangleFromGeometricObject import Rectangle

def main():
    circle = Circle(1.5)
    print("A circle", circle)
    print("The radius is", circle.getRadius())
    print("The area is", circle.getArea())
    print("The diameter is", circle.getDiameter())

    rectangle = Rectangle(2, 4)
    print("\nA rectangle", rectangle)
    print("The area is", rectangle.getArea())
    print("The perimeter is", rectangle.getPerimeter())

main() # Call the main function
```

A circle color: green and filled: True
The radius is 1.5
The area is 7.06858347058
The diameter is 3.0

A rectangle color: green and filled: True
The area is 8
The perimeter is 12

Some more information about super and sub-class

- A subclass is **not a subset** of its superclass; In fact, a subclass usually contains **more information and methods** than its superclass
- Inheritance models the is-a relationships, but **not all** is-a relationships should be modelled using inheritance
- Do not **blindly extend a class** just for the sake of reusing methods. For example, it makes no sense for a Tree class to extend a Person class, even though they share common properties such as height and weight. A subclass and its superclass **must have the is-a relationship**

Practice

forget to call super...

```
class A:  
    def __init__(self, i = 0):  
        self.i = i
```

```
class B(A):  
    def __init__(self, j = 0):  
        self.j = j
```

```
def main():  
    b = B()  
    print(b.i)  
    print(b.j)
```

```
main() # Call the main function
```

What is the problem with the above code?

Overriding methods

- A subclass **inherits** methods from a superclass
- Sometimes it is necessary for the subclass to modify the implementation of a method defined in the superclass. This is referred to as **method overriding**

Example

- The `__str__` method in the `GeometricObject` class returns the string describing a geometric object. This method can be overridden to return the string describing a circle
 - The `__str__()` method is defined in the `GeometricObject` class and modified in the `Circle` class. Both methods can be used in the `Circle` class. To invoke the `__str__` method defined in the `GeometricObject` class from the `Circle` class, use `super().__str__()`

```
class Circle(GeometricObject):
    # Other methods are omitted

    # Override the __str__ method defined in GeometricObject
    def __str__(self):
        return super().__str__() + " radius: " + str(radius)      __str__ in superclass

refer to      superclass

```

Practice

What would be the output of the following program?

```
class A:
```

```
    def __init__(self, i = 0):
```

self.i = i

```
    def m1(self):
```

```
        self.i += 1
```

```
class B(A):
```

```
    def __init__(self, j = 0):
```

super().__init__(j)

self.j = j

```
    def m1(self):
```

```
        self.i += 1
```

overriding

```
def main():
```

```
    b = B()
```

```
    b.m1()
```

```
    print(b.i)
```

```
    print(b.j)
```

```
main() # Call the main function
```

b.i=3

b.j=0

(very special)

The object class

名字是“对象”但实际是一个类
所有类的父类

- Every class in Python is descended from the **object** class
- The **object** class is defined in the Python library. If no inheritance is specified when a class is defined, its superclass is **object by default**

```
class ClassName:  
    ...
```

Equivalent

```
class ClassName(object):  
    ...
```

Methods of the object class

1. Create an obj., save it in the memory

2. Call `__init__()` automatically

因此

- The `__new__()` method is automatically invoked when an object is constructed. This method then invokes the `__init__()` method to initialize the object. Normally you should only override the `__init__()` method to initialize the data fields defined in the new class

当打印对象时，调用 `__str__()` 的返回值

- The `__str__()` method returns a string description for the object
- Usually you should override the `__str__()` method so that it returns an informative description for the object
- The `__eq__()` method returns True if 2 objects are the same

What is the output of this program?

```
class A:  
    def __init__(self, i = 0):  
        self.i = i  ⇒ x.i=8  
  
    def m1(self):  
        self.i += 1  
  
    def __str__(self):  
        return 'The content of this object is:' + str(self.i)  
  
x = A(8)  
print(x)
```

没有 call m1()

What is the output of this program?

```
class A:  
    def __new__(self):  
        print("A's __new__() invoked")  
  
    def __init__(self):  
        print("A's __init__() invoked")
```

```
class B(A):  
    def __new__(self):  
        print("B's __new__() invoked")  
  
    def __init__(self):  
        print("B's __init__() invoked")
```

```
def main():  
    b = B()  
    a = A()
```

```
main() # Call the main function
```

2

1

B's __init__() not called

"Don't touch __new__()

What is the output of this program?

```
class A:  
    def __new__(self):  
        self.__init__(self)  
        print("A's __new__() invoked")  
  
    def __init__(self):  
        print("A's __init__() invoked")
```

```
class B(A):  
    def __new__(self):  
        self.__init__(self)  
        print("B's __new__() invoked")
```

```
    def __init__(self):  
        print("B's __init__() invoked")
```

```
def main():  
    b = B()  
    a = A()
```

```
main() # Call the main function
```

a and b both None ⇒ None

多态 Polymorphism and dynamic binding

- **Polymorphism** means that the objects of different classes can be passed as arguments to the same function
- A method may be implemented in several classes along the inheritance chain
- Python decides which method is invoked at runtime. This is known as **dynamic binding**

Polymorphism

- The **inheritance** relationship enables a subclass to inherit members from its superclass with additional new members
- A subclass is a **specialization** of its superclass; every instance of a subclass is also an instance of its superclass, but not vice versa
- Therefore, when two objects share some common members, they can both be passed as arguments to the same function

Example

```
from CircleFromGeometricObject import Circle
from RectangleFromGeometricObject import Rectangle

def main():
    # Display circle and rectangle properties

    c = Circle(4)
    r = Rectangle(1, 3)
    displayObject(c)
    displayObject(r)
    print("Are the circle and rectangle the same size?",
          isSameArea(c, r))

    # Display geometric object properties
    def displayObject(g):
        print(g.__str__())

# Compare the areas of two geometric objects
def isSameArea(g1, g2):
    return g1.getArea() == g2.getArea()

main() # Call the main function
```

可能是圆的数据类
也可能是长方形的数据类

Output

```
color: green and filled: True radius: 4
color: green and filled: True width: 1 height: 3
Are the circle and rectangle the same size? False
```

Dynamic binding

继承链
Inheritance Chain

- Dynamic binding works as follows: Suppose an object o is an instance of classes C_1, C_2, \dots, C_{n-1} , and C_n , where C_1 is a subclass of C_2 , C_2 is a subclass of C_3, \dots , and C_{n-1} is a subclass of C_n
- That is, C_n is the most general class, and C_1 is the most specific class
- In Python, C_n is the object class
- If o invokes a method p , Python searches the implementation for the method p in C_1, C_2, \dots, C_{n-1} , and C_n , in this order, until it is found

某一个对象继承上层类的实现
Object

If o is an instance of C_1 , o is also an instance of C_2, C_3, \dots, C_{n-1} , and C_n .

C_n C_{n-1} C_{n-2} ... C_1 有 m_1, m_2, m_3

执行 C_1 的方法
 C_1 也有 m_1

沿着继承链 以下往上找
执行最近的

Example

- What would be the output of this program?

```
class C1:  
    def __init__(self):  
        self.f = 1  
  
    def output(self):  
        print('In C1, the f is:', self.f)
```

```
class C2(C1):  
    def __init__(self):  
        self.f = 2
```

```
    def output(self):  
        print('In C2, the f is:', self.f)
```

```
class C3(C2):  
    def __init__(self):  
        self.f = 3
```

```
class C4(C3):  
    def __init__(self):  
        self.f = 4
```

```
a=C4()  
print(a.f)  
a.output()
```

从上到下
从左到右

从上到下

Example

```
class Student:  
    def __str__(self):  
        return "Student"
```

```
def printStudent(self):  
    print(self.__str__())
```

```
class GraduateStudent(Student):  
    def __str__(self):  
        return "Graduate Student"
```

```
a = Student()  
b = GraduateStudent()  
a.printStudent()  
b.printStudent()
```

Question

- Suppose you want to modify the displayObject function in previous example to perform the following tasks:
 - Display the area and perimeter of a Circle or Rectangle instance
 - Display the diameter if the instance is a Circle, and the width and height if the instance is a Rectangle

Does this program work?

```
def displayObject(g):
    ✓ print("Area is", g.getArea())
    ✓ print("Perimeter is", g.getPerimeter())
        { print("Diameter is", g.getDiameter())
        { print("Width is", g.getWidth())
        { print("Height is", g.getHeight())
```

法1.

try

Isinstance() function

- The `isinstance()` function can be used to determine whether an object is an instance of a class
- This function determines whether an object is an instance of a class by using the following syntax

```
isinstance(object, ClassName)
```

```
from CircleFromGeometricObject import Circle
from RectangleFromGeometricObject import Rectangle

def main():
    # Display circle and rectangle properties
    c = Circle(4)
    r = Rectangle(1, 3)
    print("Circle...")
    displayObject(c)
    print("Rectangle...")
    displayObject(r)

# Display geometric object properties
def displayObject(g):
    print("Area is", g.getArea())
    print("Perimeter is", g.getPerimeter())

    if isinstance(g, Circle):
        print("Diameter is", g.getDiameter())
    elif isinstance(g, Rectangle):
        print("Width is", g.getWidth())
        print("Height is", g.getHeight())

main() # Call the main function
```

```
Circle...
Area is 50.26548245743669
Perimeter is 25.132741228718345
Diameter is 8
Rectangle...
Area is 3
Perimeter is 8
Width is 1
Height is 3
```

Practice

Private methods can't be inherited/overriden

```
class Person:  
    def getInfo(self):  
        return "Person"  
  
    def printPerson(self):  
        print(self.getInfo())
```

```
class Student(Person):  
    def getInfo(self):  
        return "Student"
```

调用类名就直接
->方法不通过
继承

```
Person().printPerson()  
Student().printPerson()
```

(a)

```
class Person:  
    def __getInfo(self):  
        return "Person"  
  
    def printPerson(self):  
        print(self.__getInfo())
```

```
class Student(Person):  
    def __getInfo(self):  
        return "Student"
```

```
Person().printPerson()  
Student().printPerson()
```

(b)

→ person

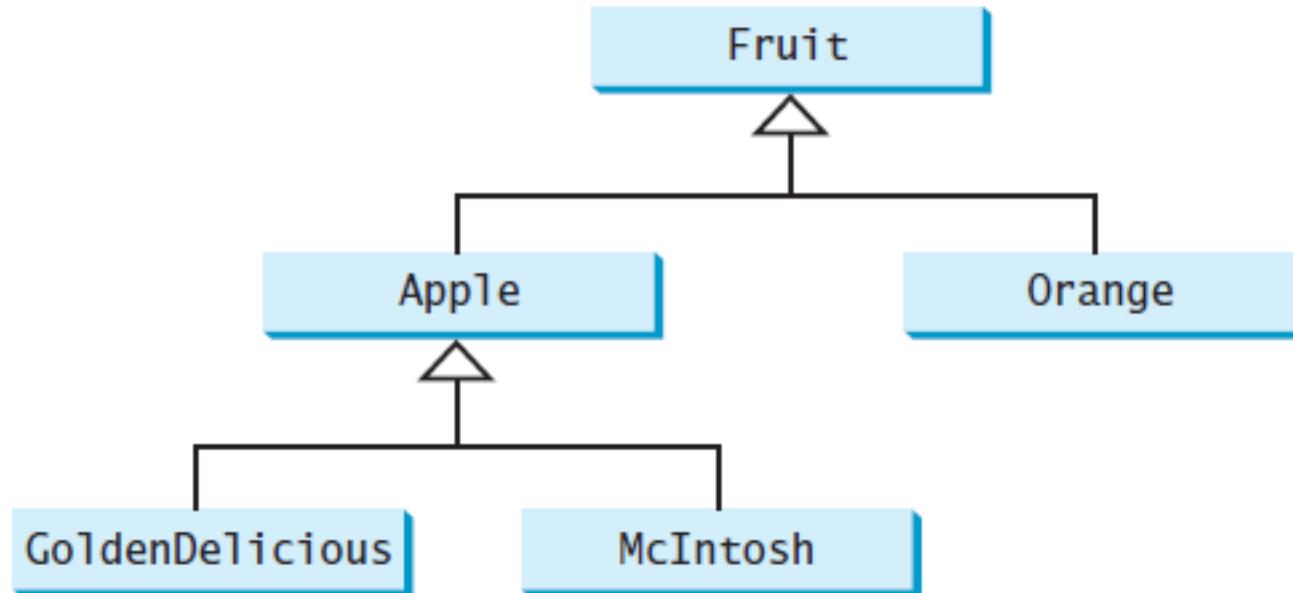

different

Output:
person & person

What would be the outputs?

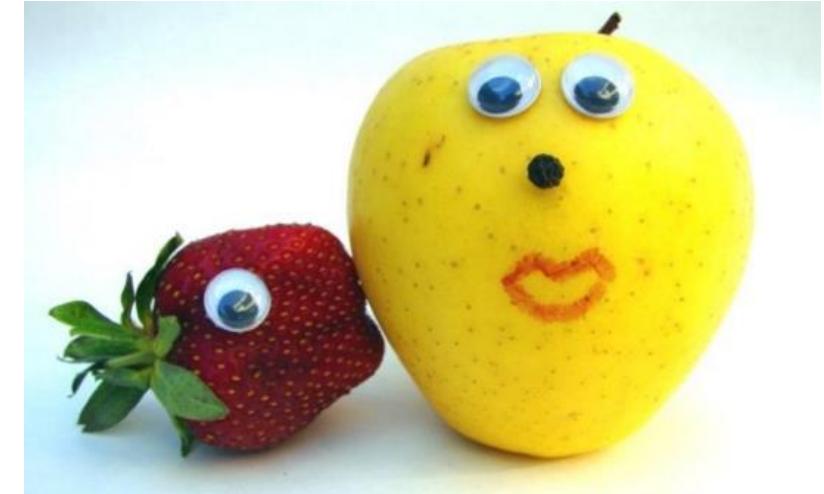

Practice

Inheritance Tree 继承树

Assume that the following statements are given:

```
goldenDelicious = GoldenDelicious()  
orange = Orange()
```

Questions

- (a) Is `goldenDelicious` an instance of `Fruit`?
- (b) Is `goldenDelicious` an instance of `Orange`?
- (c) Is `goldenDelicious` an instance of `Apple`?
- (d) Is `goldenDelicious` an instance of `GoldenDelicious`?
- (e) Is `goldenDelicious` an instance of `McIntosh`?
- (f) Is `orange` an instance of `Orange`?
- (g) Is `orange` an instance of `Fruit`?
- (h) Is `orange` an instance of `Apple`?
- (i) Suppose the method `makeAppleCider` is defined in the `Apple` class. Can `goldenDelicious` invoke this method? Can `orange` invoke this method?
- (j) Suppose the method `makeOrangeJuice` is defined in the `Orange` class. Can `orange` invoke this method? Can `goldenDelicious` invoke this method?

Practice: course class

Course	
-courseName: str	The name of the course.
-students: list	A list to store the students in the course.
Course(courseName: str)	Creates a course with the specified name.
getCourseName(): str	Returns the course name.
addStudent(student: str): None	Adds a new student to the course.
dropStudent(student: str): None	Drops a student from the course.
getStudents(): list	Returns the students in the course.
getNumberOfStudents(): int	Returns the number of students in the course.

Answer

```
from Course import Course

def main():

    course1 = Course("Data Structures")
    course2 = Course("Database Systems")

    course1.addStudent("Peter Jones")
    course1.addStudent("Brian Smith")
    course1.addStudent("Anne Kennedy")

    course2.addStudent("Peter Jones")
    course2.addStudent("Steve Smith")

    print("Number of students in course1:",
          course1.getNumberOfStudents())
    students = course1.getStudents()
    for student in students:
        print(student, end = ", ")

    print("\nNumber of students in course2:",
          course2.getNumberOfStudents())

main() # Call the main function
```

```
Number of students in course1: 3
Peter Jones, Brian Smith, Anne Kennedy,
Number of students in course2: 2
```

Answer

```
class Course:  
    def __init__(self, courseName):  
        self.__courseName = courseName  
        self.__students = []  
  
    def addStudent(self, student):  
        self.__students.append(student)  
  
    def getStudents(self):  
        return self.__students  
  
    def getNumberOfStudents(self):  
        return len(self.__students)  
  
    def getCourseName(self):  
        return self.__courseName  
  
    def dropStudent(self, student):  
        print("Left as an exercise")
```

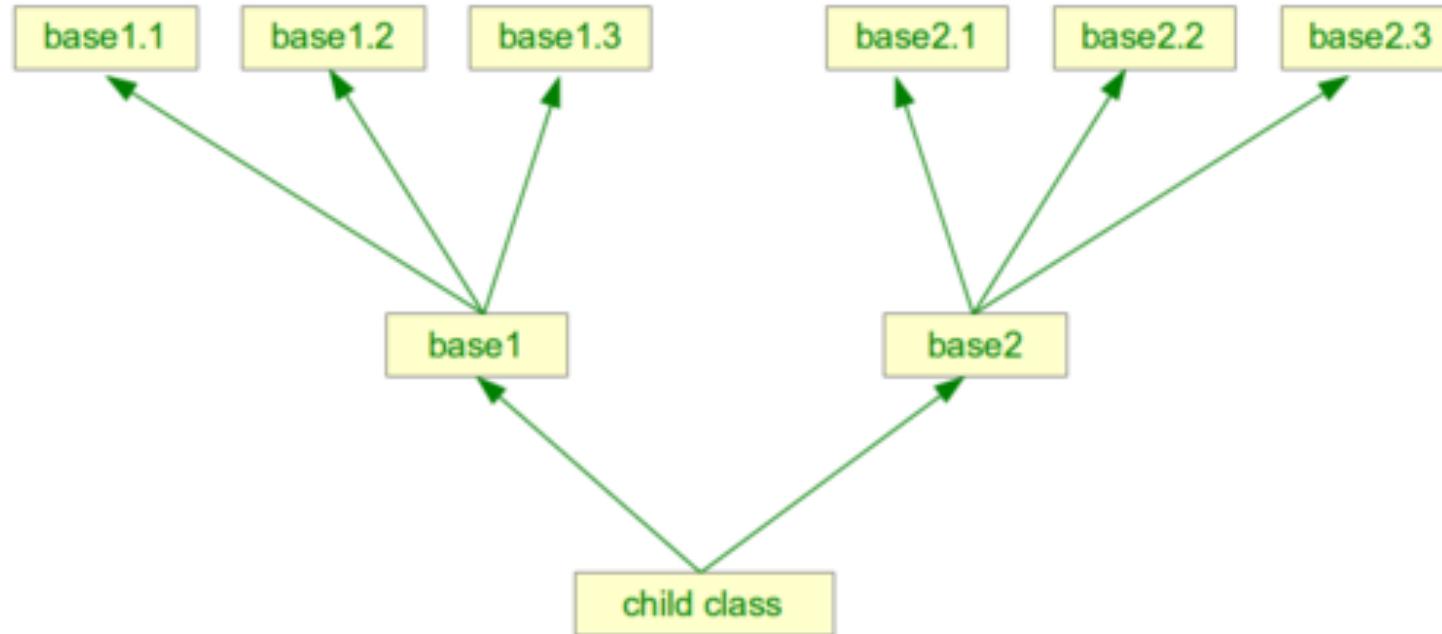

多继承

Multiple Inheritance

但 try to avoid
易犯错

- In Python, we can define new class from multiple classes
- This is called **multiple inheritance**
- Multiple inheritance is a feature in which a class can **inherit data fields** and **methods** from **more than one parent class**

Inheritance Tree

- The inheritance relationship in Python can be represented by a tree structure

Example

*super() ⇒
first superclass*

```
class A():
    def __init__(self, a=100):
        self.a=a

class B():
    def __init__(self, b=200):
        self.b=b

class C(A, B):
    def __init__(self, a, b, c=300):
        super().__init__(a)
        super().__init__(b)
        self.c=c

    def output(self):
        print(self.a) ↗
        print(self.c) ↗
        print(self.b) ✗

def main():
    c = C(1, 2, 3)
    c.output()

main() ⇒ 2, 3, None
```

Diagram illustrating the execution flow:

- The `main()` function calls `c = C(1, 2, 3)`.
- The `C` class constructor is called, with parameters `a=1`, `b=2`, and `c=3`.
- Inside the `C` constructor:
 - `super().__init__(a)` calls the `A` constructor with `a=1`. This results in `C.a=1`.
 - `super().__init__(b)` calls the `B` constructor with `b=2`. This results in `C.a=2`.
 - `self.c=c` sets `C.c=3`.
- The `C` object has attribute values: `C.a=1`, `C.a=2`, and `C.c=3`.
- The `output()` method is called on the `C` object.
- The `output()` method prints:
 - `self.a`: `2` (marked with a checkmark ↗)
 - `self.c`: `3` (marked with a checkmark ↗)
 - `self.b`: `None` (marked with a cross ✗)
- The final output is `2, 3, None`.

Example

```
class A():
    def __init__(self, a=100):
        self.a=a

class B():
    def __init__(self, b=200):
        self.b=b

class C(A, B):
    def __init__(self, a, b, c=300):
        A.__init__(self, a)
        B.__init__(self, b)
        self.c=c

    def output(self):
        print(self.a)
        print(self.c)
        print(self.b)

def main():
    c = C(1, 2, 3)
    c.output()

main()
```

Star classes

```
class star:  
    def __init__(self, name, gender):  
        print('Star init...')  
        self.name = name  
        self.gender = gender  
  
class popStar(star):  
    def __init__(self, albumList):  
        print('popStar init...')  
        star.__init__(self, 'Stephen Chow', 'Male')  
        self.albumList = albumList
